ABSTRACT

Automatic speech recognition (ASR) has progressed significantly in recent years due to large-scale datasets and the paradigm of self-supervised learning (SSL) methods. However, as its counterpart problem in the singing domain, automatic lyric transcription (ALT) suffers from limited data and degraded intelligibility of sung lyrics, which has caused it to develop at a slower pace. To fill in the performance gap between ALT and ASR, we attempt to exploit the similarities between speech and singing. In this work, we propose a transfer-learning-based ALT solution that takes advantage of these similarities by adapting wav2vec 2.0, an SSL ASR model, to the singing domain. We maximize the effectiveness of transfer learning by exploring the influence of different transfer starting points. We further enhance the performance by extending the original CTC model to a hybrid CTC/attention model. Our method surpasses previous approaches by a large margin on various ALT benchmark datasets. Further experiment shows that, with even a tiny proportion of training data, our method still achieves competitive performance.

1. INTRODUCTION

Automatic lyric transcription (ALT) systems allow for lyrics to be obtained from large musical datasets without requiring laborious manual annotation. These lyrics can then be used for many music information retrieval (MIR) tasks, including query by singing [1] and audio indexing [2]. Besides, because lyric alignment systems are very often built upon ALT models [3, 4], a strong-performing ALT model can lay a solid foundation for better audio-to-text alignment performance. Consequently, ALT is becoming an increasingly active topic in the recent MIR community.

One option for improving ALT performance is to incorporate knowledge obtained from studies involving spoken words. It is true that many studies treat ALT as a separate problem from automatic speech recognition (ASR), e.g., [3, 5–8], eschewing large-scale speech datasets and

well-developed ASR systems. However, the absence of large-scale singing datasets has impeded the construction of high-performing ALT models. While there are distinctions between sung and spoken language, e.g., sung language being less intelligible and hence harder to recognize [5, 9], they share many similarities such as having the same vocabularies and being produced by similar physical mechanisms. Therefore, we believe that it is worth investigating whether we can use knowledge and datasets from the speech domain to compensate for the inadequacy of singing datasets and bolster the performance of ALT systems.

Transfer learning methods have been found to effectively alleviate the requirement for a large amount of training data for some low-resource tasks [10, 11]. For example, speech recognition for non-native speakers [12], and machine translation for low-resource languages [13]. It is usually expensive or even impossible to re-collect as much data as for resource-plentiful tasks. In such scenarios, transfer learning helps get around the problem of insufficient data by adapting data and knowledge from related high-resource tasks or domains. In particular, parameter transfer, a transfer learning approach that adapts knowledge of parameters from the model learned in a high-resource setup to a related problem, is a simple but effective way to enhance the performance on the target domain.

In recent years, self-supervised learning (SSL) has become a new paradigm in ASR research. Several SSL methods can perform excellently with only a few hours or even a few minutes of labeled data [14–16]. Among them, wav2vec 2.0 [16] has been shown to be a particularly promising model for transfer learning [12]. wav2vec 2.0 is an effective few-shot learner that only requires a small amount of data from the target domain or problem to achieve impressive results [17, 18]. This property makes wav2vec 2.0 a promising candidate to help ALT systems overcome the issue of limited training data by transferring speech representation knowledge to the singing domain.

The contributions of this paper contain four aspects:

- We propose an ALT solution that takes advantage of the similarities between spoken and singing voices. This is achieved by performing transfer learning using wav2vec 2.0 on singing data after pretraining and finetuning on speech data.
- We maximize the effectiveness of transfer learning

by exploring the influence of different transfer starting points. We show that both pretraining and fine-tuning on speech data contribute to the high performance of our ALT model.

- We further enhance the system’s performance by extending the original connectionist temporal classification (CTC) model to a hybrid CTC/attention model for better convergence and more accurate decoding.
- We surpass previous methods on various benchmark ALT datasets, including DSing [5], DALI [19, 20], Jamendo [21], Hansen [22], and Mauch [23]. Our method outperforms previous results by about 25% relative WER reduction on average. We further show that with less than one-tenth of labeled singing data, our method can achieve state-of-the-art results on the test split of DSing, demonstrating its effectiveness in low-resource ALT setups.

2. RELATED WORK

2.1 Automatic Lyric Transcription

Recent progress in lyric transcription has been mainly driven by three factors. First, the construction and curation of datasets containing aligned audio and lyrics, including DAMP Sing! 300x30x2 [5, 24] and DALI [19, 20], lay the foundation for data-driven ALT models. Second, the design of ALT acoustic models benefits from architectures of automatic speech recognition (ASR) models, and can be further improved by adopting singing domain knowledge as inductive bias. Representative work includes TDNN-F with its variants [3, 5–7] and vanilla/convolution-augmented Transformers [8, 25, 26]. Third, through data augmentation methods such as adjusting speech data to make it more “song-like” [27] or synthesizing singing voice from speech voice [25, 26], more training data can be created for ALT models, thus alleviating the data sparsity problem.

2.2 Self-supervised speech representation learning

The success of deep learning methods is highly related to whether the learned representations are powerful. Although supervised learning still dominates the speech representation learning field, it has several drawbacks. For example, substantial amounts of labeled data are required to train supervised learning ASR models [15, 16]. Moreover, representations obtained through supervised learning tend to be biased to specific problems and are thus difficult to extend to other applications [28].

To mitigate the above problems, a series of self-supervised learning (SSL) frameworks for speech representation learning have emerged, e.g., Autoregressive Predictive Coding (APC) [29], Contrastive Predictive Coding (CPC) [15], and Masked Predictive Coding (MPC) [14, 30, 31]. Moreover, wav2vec 2.0 takes advantage of both CPC and MPC to conduct self-supervised learning and has

become the paradigm for the ASR task [16]. wav2vec 2.0 has been also widely adopted as the feature extractor for other speech-related applications, e.g. speech emotion recognition [32, 33], keyword spotting [34], speaker verification and language identification [35], demonstrating that speech representations learned from wav2vec 2.0 are robust and transferable for downstream tasks.

3. METHODOLOGY

In this section, we firstly elaborate on the structure of wav2vec 2.0 [16]. Then we explain the training process of wav2vec 2.0 in the automatic speech recognition (ASR) task. Finally, we introduce our transfer learning method for applying wav2vec 2.0 in the automatic lyric transcription (ALT) task.

3.1 Structure of wav2vec 2.0

As shown in Fig. 1, wav2vec 2.0 is built with a CNN-based feature encoder, a Transformer-based context network, and a quantization module. For raw audio inputs x with a sampling rate of 16 kHz, the feature encoder accepts x and obtains the latent speech representations z . The feature encoder has seven blocks, each of which includes a 1D temporal convolution with 512 channels followed by layer normalization [36] and GELU activation [37]. The kernel sizes of convolutions in seven blocks are $\{10, 3, 3, 3, 3, 2, 2\}$ while the strides are $\{5, 2, 2, 2, 2, 2, 2\}$. Consequently, $z \in \mathcal{R}^{T \times 1024}$ are 2D representations with a frequency of 49 Hz. To exploit the temporal relationship among different frames of latent representations, z are further fed into the context network, which is parameterized by 12 Transformer blocks [38]. Each block has a multi-head attention module with 16 attention heads and a Feed-Forward Network (FFN) with a hidden dimension of 4,096. A convolutional layer is adopted as the relative positional embedding. The resulting context representations $c \in \mathcal{R}^{T \times 1024}$ are the features extracted from the audio signal and used for downstream tasks.

In addition to being fed into the context network, z are also accepted by a quantization module, which learns quantized speech representations q , thus facilitating the self-supervised training. The quantization module utilizes Gumbel softmax [39] to enable fully differentiable training and product quantization [40] to increase codebook size. The number of codebooks is 2, and each codebook has 320 entries.

3.2 Speech-Domain Training of wav2vec 2.0

3.2.1 Pretraining

wav2vec 2.0 is pretrained through an SSL method [16] on large-scale unlabeled speech data, as displayed in Fig. 1(a). Before latent representations z are fed into the context network, several consecutive frame sequences are randomly masked. Specifically, all frames of z are sampled as starting indices with the probability of 0.065, whose subsequent 10 frames are masked. The masked frames are

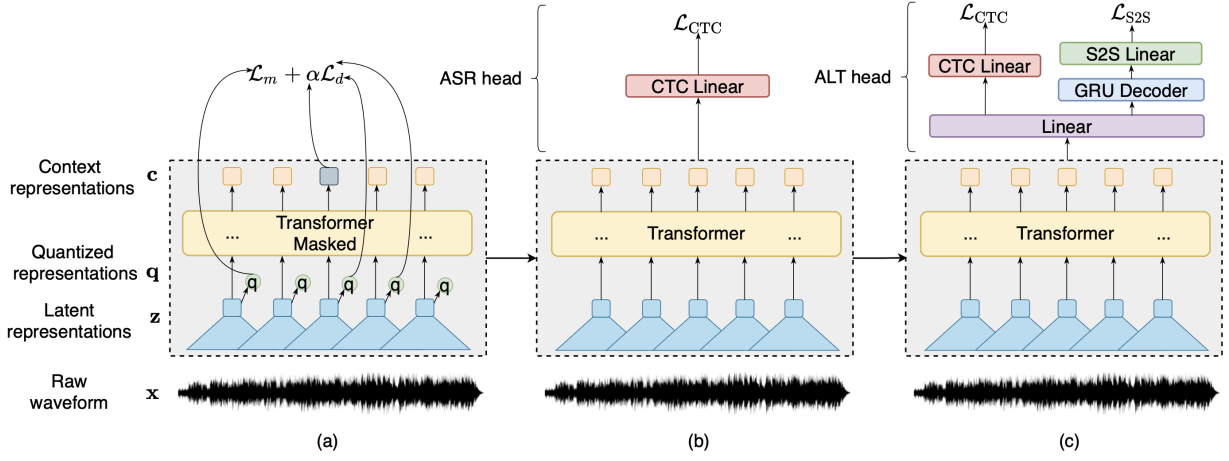

Figure 1. An overview of our training framework. (a) Pretraining on speech data. (b) Finetuning on speech data. (c) Transferring on singing data.

replaced by a trainable vector. wav2vec 2.0 is trained by optimizing the combination of contrastive loss and diversity loss $\mathcal{L}_m + \alpha \mathcal{L}_d$. The contrastive objective is defined as:

$$\mathcal{L}_m = -\log \frac{\exp(\text{sim}(\mathbf{c}_t, \mathbf{q}_t)/\kappa)}{\sum_{\tilde{\mathbf{q}} \sim \mathbf{Q}_t} \exp(\text{sim}(\mathbf{c}_t, \tilde{\mathbf{q}}_t)/\kappa)} \quad (1)$$

where \mathbf{c}_t is t -th frame of context representations, \mathbf{Q}_t represents all possible quantized representations, κ is set as 0.1 and sim refers to the cosine similarity. The diversity loss \mathcal{L}_d is designed to encourage the usage of all entries in codebooks. We refer readers to [16] for more details.

3.2.2 Finetuning

The process of finetuning requires the participation of labeled speech data. As shown in Fig. 1(b), the quantization module in wav2vec 2.0 is disabled, and a linear layer (ASR head) is added on top of the Transformer. The whole model is trained by optimizing the connectionist temporal classification (CTC) loss \mathcal{L}_{CTC} [41]. Suppose the ground-truth transcription is \mathbf{w}^* , which is a sequence of character tokens. The CTC loss is defined as:

$$\mathcal{L}_{\text{CTC}} = -\log \sum_{\boldsymbol{\pi} \in \mathcal{B}^{-1}(\mathbf{w}^*)} \prod_{t=1}^T p(\boldsymbol{\pi}_t | \mathbf{f}_t) \quad (2)$$

where \mathbf{f}_t refers to \mathbf{c}_t in this stage, T is the number of frames, \mathcal{B} is a function to map an alignment sequence $\boldsymbol{\pi}_{1:T}$ to $\mathbf{w}_{1:N}^*$ (where N represents the number of character tokens) by removing duplicate characters and blanks while its inverse function $\mathcal{B}^{-1}(\mathbf{w}^*)$ refers to all the CTC paths mapped from \mathbf{w}^* . For speech data, there are 31 tokens for character targets including 26 letters, quotation mark, word boundary token, $\langle \text{bos} \rangle$, $\langle \text{eos} \rangle$, and CTC blank token. The probability $p(\boldsymbol{\pi}_t | \mathbf{f}_t)$ is computed by the CTC linear layer followed by a softmax operation.

Besides the supervised CTC loss, pseudo-labeling is also adopted during finetuning. It has been proven that self-training and pretraining are complementary for the ASR task [42].

3.3 Singing-Domain Transferring of wav2vec 2.0

3.3.1 From CTC to CTC/attention

To transfer the trained wav2vec 2.0 from the speech domain to the singing domain, we retain the weights of the feature encoder and the context network after pretraining and finetuning on speech data and then remove the quantization module. Furthermore, inspired by [43], we extend the original CTC system into a hybrid CTC/attention system through the addition of an ALT head on top of wav2vec 2.0 instead of a single CTC linear layer (Fig. 1(c)).

The context representations \mathbf{c} are first fed into a linear layer followed by a leaky ReLU activation layer to obtain the features \mathbf{f} . Then \mathbf{f} are sent to two network branches. One branch is a CTC linear layer, which aims to compute $p(\boldsymbol{\pi}_t | \mathbf{f}_t)$ as explained in sec. 3.2.2. Another branch is an attention-based GRU decoder [44] followed by a sequence-to-sequence (S2S) linear layer. The GRU decoder has a single layer with a hidden dimension of 1,024 and an attention dimension of 256, and it utilizes location-aware attention mechanism. The decoder and S2S linear layer autoregressively compute the probability $p(\mathbf{w}_n | \mathbf{w}_{<n}, \mathbf{f}_{1:T})$, $n = 1, 2, \dots, N$.

3.3.2 Training and Evaluation

During the training on singing data, wav2vec 2.0 and the ALT head are trained through the combination of CTC loss [41] and S2S loss [45]:

$$\mathcal{L}_w = \lambda_a \mathcal{L}_{\text{CTC}} + (1 - \lambda_a) \mathcal{L}_{\text{S2S}} \quad (3)$$

$$\mathcal{L}_{\text{S2S}} = -\log \prod_{n=1}^N p(\mathbf{w}_n^* | \mathbf{w}_{<n}^*, \mathbf{f}_{1:T}) \quad (4)$$

where λ_a is a hyper-parameter to balance the CTC loss term and S2S loss term. To overcome catastrophic forgetting, we adopt a smaller learning rate for wav2vec 2.0 compared to that of the ALT head.

To evaluate the performance of the trained model, the most likely lyrics are predicted using beam search:

$$\begin{aligned} \mathbf{w}' = \arg \max_{\mathbf{w}} \lambda_b \log \sum_{\boldsymbol{\pi} \in \mathcal{B}^{-1}(\mathbf{w})} \prod_{t=1}^T p(\boldsymbol{\pi}_t | \mathbf{f}_t) \\ + (1 - \lambda_b) \log \prod_{s=1}^S p(\mathbf{w}_s | \mathbf{w}_{<s}, \mathbf{f}_{1:T}) \\ + \lambda_c \log p_{LM}(\mathbf{w}) \end{aligned} \quad (5)$$

where λ_b and λ_c are two hyper-parameters in the decoding process. The language model is implemented by a 3-layer LSTM. The characters are firstly projected to embeddings, and then fed into the LSTM with a hidden dimension of 2,048 to obtain RNN features. Finally, the RNN features are accepted by a 3-layer MLP with a hidden dimension of 1,024 to output the probability $p_{LM}(\mathbf{w})$.

4. EXPERIMENTS

4.1 Datasets and preprocessing

We use various accessible mainstream lyric transcription datasets for our experiments, including DALI [19, 20], Hansen [22], Mauch [23], Jamendo [21], and a curated version of DAMP Sing! 300x30x2 [24] called DSing [5]. The train/development/test splits in our experiments are defined as follows. For the DSing dataset, we use the same split configuration proposed in [5]. Specifically, there are three different sizes of training sets (DSing1, DSing3, DSing30), as well as a development set DSing^{dev} and a test set DSing^{test}. As for the DALI dataset, we divide all publicly available audio in DALI v2 [20] into training and development subsets (DALI^{train} and DALI^{dev} respectively).¹ We use DALI^{test} [7], a subset of DALI v1 [19], as a test set for experiments involving DALI. The full Hansen, Mauch, and Jamendo datasets are used as additional out-of-domain test sets. In the training and development splits of the DALI dataset, songs that overlapped with any of our test sets are removed for more objective testing.

The speech data used to pretrain and finetune the wav2vec 2.0 is initially monophonic. We therefore expect wav2vec 2.0 to extract better representation features for singing data if it is given monophonic audios as the inputs. Thus, we extract vocal parts from all of the polyphonic recordings in DALI, Mauch, and Jamendo datasets using Demucs v3 [46], which is the state-of-the-art source separation model that achieved the first rank at the 2021 Sony Music DemiXing Challenge (MDX). This ensures that we are consistent with the pretraining configuration and minimize the interference of musical accompaniment. Next, we perform utterance-level segmentation on all audios according to their annotations. Utterances with obvious faulty annotations are removed (e.g., utterances labeled

¹ At the time of this research, some audios are not retrievable through their YouTube links in the public-available metadata. Although audios containing both the same titles and artist names can be found online, we cannot guarantee they perfectly match the annotations for the original audio versions in DALI. Discarding invalid audio is only performed for the training and the development sets.

Split	Dataset	# Utt.	Total Dur.
Train	DSing1	8,794	15.1 h
	DSing3	25,526	44.7 h
	DSing30	81,092	149.1 h
	DALI ^{train}	268,392	183.8 h
Dev	DSing ^{dev}	482	41 min
	DALI ^{dev}	1,313	55 min
Test	DSing ^{test}	480	48 min
	DALI ^{test}	12,471	9 h
	Jamendo	921	49 min
	Hansen	634	34 min
	Mauch	878	54 min

Table 1. Statistics of segmented utterance-level datasets.

as several words but have shorter than 0.1 s duration). The statistics of all datasets after utterance-level segmentation are listed in Table 1. We notice that the average utterance duration of DSing is longer than DALI (6.52 s vs. 2.47 s). Finally, lyric texts are normalized by converting all letters to upper case, converting digits to words, discarding out-of-vocabulary characters, discarding meaningless lines (e.g., “**guitar solo**”), and removing redundant space.

4.2 Experiment setup

Our experiments are conducted through SpeechBrain toolkit [47]². We load the weights of wav2vec 2.0 after pretraining and fine-tuning³ on speech data into our model and randomly initialize the weights of the ALT head. During the transferring, we downsample all audios to 16 kHz and average both channels of stereo audio signals since wav2vec 2.0 only accepts mono-channel inputs with a 16 kHz sampling rate. Then the singing data is augmented through SpecAugment [48]. wav2vec 2.0 and ALT head are trained using Adam optimizer [49]. The initial learning rates of ALT head and wav2vec 2.0 are 3×10^{-4} and 1×10^{-5} respectively. Learning rates are scheduled using the Newbob technique, with annealing factors of 0.8 and 0.9 respectively. The batch size is set as 4, and hyperparameter λ_a is set as 0.2 during the experiments. We conduct our experiments on 4 RTX A5000 GPUs. Utterances with a duration longer than 28 seconds are filtered out during training to prevent the out-of-memory issue. This filtering is not performed during the evaluation for a fair comparison with other existing methods.

We firstly utilize DSing30 to train the whole model for 10 epochs. We evaluate the performance of our model on DSing^{dev} after each epoch. Finally, the best model is selected to be evaluated on the test split DSing^{test}. Word error rate (WER) is adopted as the evaluation metric. The RNNLM is trained for 20 epochs using an Adam optimizer [49] on texts of DSing30 split and validated on the DSing^{dev} split after each epoch. The learning rate is 1×10^{-3} and the batch size is 20. During the decoding, the beam size is 512, and the hyper-parameters λ_b and λ_c are 0.4 and 0.5, respectively.

² The code will be released after the paper’s acceptance.

Table 2. WERs (%) of various ALT systems on different singing datasets. “-” refers to “non-applicable”. We use **bold face** to highlight the best results, and underline to mark the second-best results.

Next, we continue training the ALT model on DALI^{train} split for 4 epochs. The weights of learnable parameters are initialized using the model trained on DSing30. After training, we evaluate the model on DALI^{test} as well as the Hansen, Mauch, and Jamendo datasets. The configuration of RNNLM is the same as above, except that we utilize texts of both DSing30 and DALI^{train} to train the model. To decode the lyrics, we set the beam size as 512 and the hyper-parameters λ_b as and λ_c as 0.3 and 0.2, respectively.

5. RESULTS

5.1 Comparison with the state-of-the-art

We compare the performance of the proposed method with previous approaches, as shown in Table 2. We note that our method outperforms all previously published results on all the evaluation datasets. Our method achieve 5.36%, 1.97%, 11.26%, 1.81%, 18.07%, 8.85% absolute WER reduction on the DSing^{dev}, DSing^{test}, DALI^{test}, Jamendo, Hansen, and Mauch datasets, compared with the best results among all the previous state-of-the-art approaches respectively. Especially, on DALI^{test}, Hansen, and Mauch datasets, our method significantly exceeds MSTRE-Net [7] by average 12.73% absolute WER.

5.2 Effects of pretraining & finetuning on speech data

As shown in Fig. 1, wav2vec 2.0 is pretrained and finetuned on speech data before transferring to singing data. The feature representation knowledge learned from speech data is the key to the success of our method. To validate this statement, we conduct ablation studies by comparing the proposed method to two alternative configurations. The first alternative configuration is that we randomly initialize the weights of wav2vec 2.0 and ALT head and then train the whole model on the DSing dataset as per the experiment setup in sec. 4.2. Note that the first alternative has no transfer learning from the speech domain (without pretraining and finetuning). The second alternative configuration is that we only perform pretraining on speech data⁴ without finetuning before transferring the wav2vec 2.0 to the singing domain.

We evaluate the above training configurations on the DSing dataset. First, we show the curves of training loss

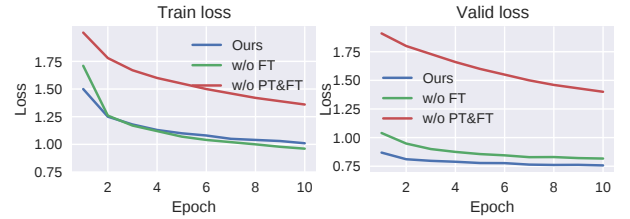

Figure 2. Comparison of different training configurations. “w/o PT & FT” refers to without pretraining and finetuning on speech data. “w/o FT” refers to without finetuning on speech data. (Left) Training loss of all configurations for the first 10 epochs; (Right) validation loss of all configurations for the first 10 epochs.

Method	DSing ^{dev}	DSing ^{test}
Ours	12.34	12.99
- Finetuning	12.64 (+ 0.30)	14.58 (+ 2.59)
- Pretraining	35.61 (+24.27)	39.13 (+26.14)

Table 3. WERs (%) of different training configurations on DSing dataset.

and validation loss (loss of the development set) during the training for the first 10 epochs in Fig. 2. The losses are computed through Eq. 3. We observe that without pretraining and finetuning on speech data, the training loss and validation loss are much higher than the other two training configurations. In addition, its training is also more difficult to converge. When we enable the pretraining but disable the finetuning on speech data, the behavior of the training loss is similar to the proposed configuration, except that the training loss is higher at the beginning. However, the validation loss in this setup is higher than that of the proposed configuration. This difference indicates that finetuning on speech data enhances the generalization ability of wav2vec 2.0.

We continue training both alternatives until convergence and display the resultant performances in Table 3. We note that without finetuning on speech data, the performance drops by 0.30% higher WER on DSing^{dev} and 2.59% higher WER on DSing^{test}. Furthermore, without both pretraining and finetuning on speech data, the performance degrades severely as WERs on DSing^{dev} and

⁴ <https://huggingface.co/facebook/wav2vec2-large-lv60>

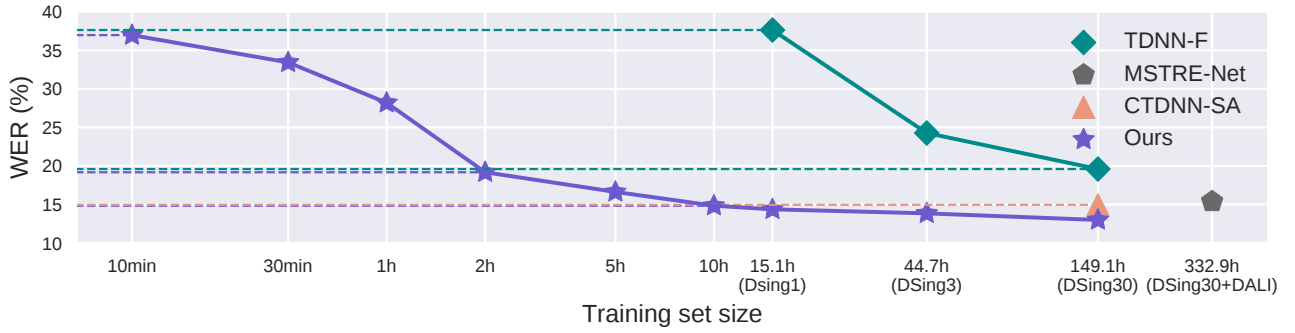

Figure 3. Comparison of different training set sizes on the DSing dataset.

Method	DSing ^{dev}	DSing ^{test}
CTC	19.86	20.99
+ S2S	15.63 (-4.23)	16.95 (-4.04)
+ LM	12.34 (-7.52)	12.99 (-8.00)

Table 4. WERs (%) of CTC model and hybrid CTC/attention model on DSing dataset.

DSing^{test} increase by 24.27% and 26.14% respectively, compared to the proposed configuration. The results are consistent with our observations in Fig. 2. Therefore, we conclude that pretraining on speech data plays a significant role in transferring wav2vec 2.0 to the singing domain. Although finetuning on speech data is less critical than pre-training, it also contributes to the generalization ability of wav2vec 2.0 in the singing domain.

5.3 Effects of extending CTC to CTC/attention model

To validate the effectiveness of changing from ASR head to ALT head (as in Fig. 1), we compare the performances of our hybrid CTC/attention model with its CTC version, as shown in Table 4. We set $\lambda_b = 1$ in Eq. 5 to disable the branch of the GRU decoder and the S2S linear during the decoding. When $\lambda_c = 0$, the RNNLM is disabled.

We observe that the hybrid CTC/attention model achieves better performance by 4.23% and 4.04% WER on DSing^{dev} and DSing^{test} respectively than its CTC counterpart, which demonstrates the superiority of our ALT head design. Furthermore, we evaluate the benefits brought by the language model and find that the final model leads to 3.29% and 3.96% further absolute WER improvements compared to the hybrid CTC/attention model.

5.4 Effectiveness of transfer learning in low-resource scenarios

To explore the effectiveness of our transfer learning method in reducing the amount of required training data, we conduct an ablation study with different training set sizes. We first train our model on DSing30, DSing3, and DSing1, respectively, to observe the performance differences. We then further reduce the training set size to a minimum of 10 minutes to create more demanding

low-resource setups. We report the WERs achieved on DSing^{dev} and DSing^{test} as the performance measure. Since the 10-minute and 30-minute datasets are too small for the training of the GRU decoder, WERs are computed according to the CTC outputs only.

As shown in Fig. 3, our method achieves 14.84% WER with only 10 hours (about 6.7% size of DSing30) of labeled singing data, which surpasses the state-of-the-art results of 14.96% WER achieved by CTDNN-SA [6] trained on DSing30. It also has better performance with only 2 hours of training data (about 1.3% size of DSing30) than TDNN-F [5] trained on DSing30 (19.18% vs. 19.60% WER). Furthermore, we also substantiate the potential of ultra-low resource ALT: with only 10 minutes of data (1.1% size of DSing1), our method achieves better results than TDNN-F trained on DSing1 (36.97% vs. 37.63% WER). These results demonstrate the feasibility of achieving competitive results with much less training data by adopting the representation knowledge from the speech domain.

6. CONCLUSION

We have introduced a transfer learning approach for the automatic lyric transcription (ALT) task by utilizing the representation knowledge learned by self-supervised learning models on speech data. By performing parameter transfer on wav2vec 2.0 towards the singing domain and extending the original CTC model to a hybrid CTC/attention version, we achieved significant improvement compared to previous state-of-the-art methods on various singing datasets. We demonstrated that both pretraining and finetuning on speech data contribute to the final ALT performance and that pretraining brings more performance gains than finetuning on speech data. Additionally, our method still showed competitive performance using only a tiny proportion of training data, indicating its potential in low-resource scenarios.
